

* BUILDER'S NOTEBOOK

A quiet week of hardening

■ What shipped

This was a light week for merged work – one pull request landed – but it sits on top of a release that went out the day before this log's window opened, so it's worth covering both.

Desktop v1.1.1 is out

On September 9 we published [Allternit Desktop v1.1.1](#). This is the fully bundled build: the platform UI (a Next.js static export), the Rust API backend (local on `:8013`), and the Gizzi AI runtime (Bun, local on `:4096`) all ship inside the installer. Once it's installed, nothing needs the network.

- macOS builds for both arm64 and x64, plus a Windows installer
- Auto-updates enabled, so existing installs will get prompted when the next build lands

Service worker cache guard

The only merge this week was PR #247 (`fix/sw-cache-guard`). The name is terse, but the shape of the fix is clear: a guard around the service worker's cache behavior. Service workers sit between the app and the network and decide what gets served from local cache versus fetched fresh – without a guard in the right place, a stale cached response can be served when a fresh one was expected, or the cache can interfere with content that should never have been cached at all.

Given that the desktop app serves a static UI that loads `https://ai.allternit.com`, cache correctness matters twice over: a stale service worker cache in the desktop shell could pin a user to an old version of the interface even after the API and runtime underneath it have moved forward.

■ Why it matters

Most of this week's value is in the release, and the release is about a single property: the app works without the internet. That's not a convenience feature for our user base – engineers running local models, people on unreliable connections, anyone who wants the AI runtime on their own machine without a dependency on a hosted service. Bundling all three components (UI, Rust API, Bun runtime) into one installer means the "local" in "local AI" is actually true end to end. The UI talks to a backend on `localhost:8013`, the runtime on `:4096`, and nothing leaves the machine unless you tell it to.

The cache guard fits the same theme. Local-first software has a specific failure mode that hosted software doesn't: because everything is expected to work offline and from local resources, stale state is harder to notice and harder to clear. A user on a hosted app refreshes and gets the new build. A user with a desktop app and an aggressive service worker cache might keep running last month's UI against this week's runtime – and the symptoms of that mismatch (subtle, hard to reproduce, "works on my machine" in the worst way) are exactly the kind of bug report that eats an afternoon. Putting a guard around the cache path is cheap insurance against that class of problem.

One honest note: with a single merge in seven days, there's not much more we can responsibly say about this week's code changes. We'd rather ship a short, accurate log than pad it with speculation about what a terse commit message might mean. If you want the full detail, the diff in PR #247 is small and readable.

■ What's next

Nothing in this week's activity points to larger in-flight work, so we're not going to invent a roadmap section. What we can say: with v1.1.1 freshly out and auto-updates enabled, the feedback loop on the bundled build is now open. If you're running the desktop app and see anything odd – especially around the UI version you're being served versus what's current – that's exactly the failure mode the cache guard is meant to address, and a report with your app version and install date is genuinely useful.

We'll be back next week with whatever the repository gives us.

ABOUT THIS EDITION

This was a light week for merged work – one pull request landed – but it sits on top of a release that went out the day before this log's window opened, so it's worth covering both.
